# How I Built My Pokémon Card Binder (Without Knowing How to Code)

October 2026

## The short version

I built my own app that tracks my Pokémon card collection. It runs on a computer in my house, and I open it on my phone from anywhere. I can't write code. An AI assistant wrote every line of it while I described what I wanted, tried each version, and said what to change.

It started as a spreadsheet of the cards I owned from one set. About a week and more than 75 small updates later, it does all of this:

- Shows every card in a set, in color if I own it and grey if I still need it
- Prices each card from recent real sales and keeps a price history
- Lays out a binder page by page, like a real binder, with a cover
- Searches every English card ever made and adds it to any binder
- Logs what I paid, keeps photos of my copies, and makes a shopping list
- Opens on a home page with a shelf of all my binders

The skill that mattered wasn't programming. It was knowing what I wanted, trying every version, and explaining clearly what was wrong or missing. If you can describe a problem to a friend, you can do this.

## How it works, in one picture

Think of it as working with a builder who never gets tired:

1. **You describe** what you want, in normal words.
2. **The AI builds it** and tells you exactly what to click or type.
3. **You try it** and report what happened, good or bad.
4. **Repeat.** Each round makes it a little better.

You never have to understand the code. You only have to understand what you want the app to do, and notice when it doesn't.

## What you need

| Piece | What it does | What I used | Easiest choice for you |
|---|---|---|---|
| An AI assistant | Writes the code and walks you through every step | Claude | Any well-known AI chat assistant. Most are free to try. |
| A computer | Runs your app | A home server that's always on | The laptop or desktop you already have, Windows or Mac |
| Python | The free program that runs the code the AI writes | Python | Python from python.org (the AI will walk you through it) |
| A private connection (later) | Lets your phone open the app when you're away from home | Tailscale | Tailscale, free for personal use |

You don't need all four on day one. Start with the AI and your own computer. Add the rest when you want it.

Later on, I also put my code here on GitHub so the app can update itself when I tap a button and confirm. You don't need that to start.

## Step by step

### Step 1: Set up the AI with a project

Sign up for an AI chat assistant. I used Claude, but the steps in this guide work much the same in others.

If your assistant lets you create a **project** (some call it a workspace or something similar), make one for your app. A project is like a folder for one idea: it remembers your instructions every time you start a new chat inside it, so you don't have to explain yourself over and over.

A project has a place for **instructions**. Write a few lines there about you and your app, like:

- What the app is for, in one sentence
- That you don't code and are new to computers, so it should use plain language and explain any technical word
- That it should give you one step at a time and wait for you to say "done"
- That your data should stay on your own computer, in its own folder, separate from the code

If your assistant has no projects, paste those lines at the start of each new chat instead. Either way, this was the single most useful thing I did. It's how the AI knew I don't code, how I like

things explained, and what rules my app follows.

### Step 2: Describe your idea

Start a new chat inside the project and describe your idea: what the app should do, in two or three short points. If you have a spreadsheet, a photo, or a screenshot of something you like, attach it. Showing beats describing. Then ask it to walk you through building it one step at a time.

Keep the first version small. Mine was "show my cards and what they're worth." Everything else came later.

### Step 3: Install Python (one time only)

The AI will tell you to do this, but here's what to expect:

1. Go to **python.org**, click **Downloads**, and download the version for your computer.
2. Open the file you downloaded and click through the installer.
3. **Windows only:** on the first screen, tick the box that says **Add python.exe to PATH** before you click Install. If you miss it, things won't work later. (If that happens, just tell the AI. It's a common fix.)

### Step 4: Open the Terminal

The Terminal is a plain text window where you type commands. It looks scary, but you'll only ever copy and paste what the AI gives you.

- **Windows:** click Start, type **Terminal** (or **Command Prompt**), and press Enter.
- **Mac:** press Command and Space together, type **Terminal**, and press Enter.

When the AI gives you a command, copy it, paste it into the Terminal, and press Enter. Then copy whatever the Terminal shows back and paste it to the AI, even if it looks like gibberish. That text is how the AI sees what happened.

### Step 5: Run your app and open it

The AI will give you a few files, tell you which folder to save them in, and give you one command to start the app. Then open your web browser (Chrome, Safari, Edge) and type the address it gives you, usually something like **http://localhost:8080**. Your app appears in the browser like a website, but it's running on your own computer.

Leave the Terminal window open while you use the app. Closing it stops the app.

## Step 6: Try everything and report back

Click every button. Try it on your phone too (see Step 7). Then tell the AI:

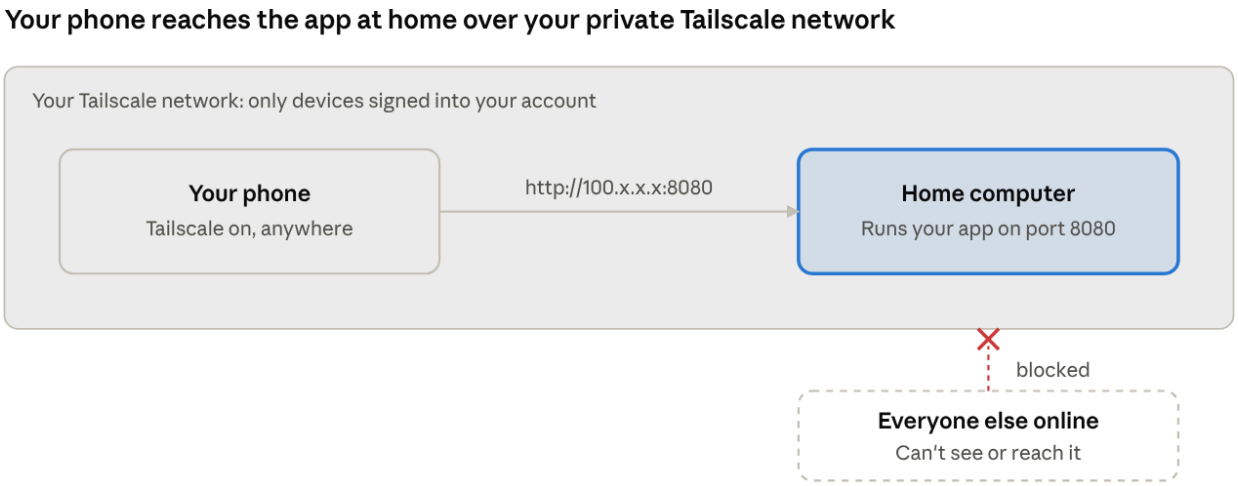

- What worked
- What's broken (a screenshot is best)
- What's confusing
- One thing you'd like next

Ask for **one change at a time**. "Make cards I don't own grey." "Add a button that marks a card as owned." Small requests are easier to check and easier to undo.

## Step 7: Open it on your phone

**At home:** your phone can open the app over your Wi-Fi. Ask the AI how to find your computer's address on your home network.

**Away from home:** use Tailscale. It makes your phone and your computer act like they're on the same Wi-Fi, even when you're miles away. Only devices signed into your Tailscale account can see each other, so your app stays private. The usual alternative, opening your home network to the internet, is risky and takes real know-how. Tailscale skips all of that.

### Setting it up (about 10 minutes):

1. Go to **tailscale.com** and sign up with a Google, Microsoft, or Apple account.
2. Install the Tailscale app on the computer running your app and sign in.
3. Install the Tailscale app on your phone and sign in with the same account.
4. In the Tailscale app, find your computer in the device list. It has an address that starts with **100.**, like 100.101.102.103.

5. On your phone, with Tailscale switched on, open the browser and type that address plus your app's number, like **http://100.101.102.103:8080**.

Type **http://** at the front. Some browsers otherwise try a secure connection the app doesn't have and show an error.

One catch: the app only works while that computer is on and awake. Later you can move it to an old laptop you leave running, or a home server like mine. Ask the AI to help when you're ready.

### Step 8: Keep going

Every feature in my binder came from using it and thinking "it would be nice if..." Write those thoughts down and bring them to the AI one at a time.
